

Root Pruning

The most critical pre-transplant step in the transplant process is root pruning.

Root Pruning

A 2-3 foot trench will be dug around the tree just inside of its determined final root ball size. As the trench is being dug the roots will be hand trimmed with precision to make sure the roots have every opportunity to heal and begin re-growth. At this time, the tree is treated with a root stimulator.

Root Pruning

Once the root system has been pruned, the rootball is watered and backfilled completely.
